20. ABSTRACT (Continue on reverse side if necessary and identify by block number) Vibration and acoustic measurements were made on an OH-6A helicopter equipped with a XM-27 armament system to determine the vibration and acoustic environment throughout the vehicle. Tape recordings from 60 accelerometers and 11 micro- phones were made during all flight conditions including gunfire. Spectrum anal- yses were performed to obtain vibratory double amplitude (DA), acceleration power spectral density (PSD), and sound pressure level (SPL), versus frequency.

FOREWORD

AD B003236
This effort was planned and conducted jointly by the Dynamics Technology Applications Branch, Vehicle Dynamics Division, Air Force Flight Dynamics Laboratory (AFFDL), Wright-Patterson AFB, Ohio, and the Mechanical Engineering Support Services Department, R&D Directorate, U. S. Army Electronics Command (ECOM), Fort Monmouth, New Jersey.

The investigation was conducted under Air Force Flight Dynamics Laboratory Project 1472, Dynamic Measurement and Analysis Technology for Military Vehicles, Task 1472-01, Dynamic Testing of Flight Vehicles, Work Unit 1472-01-003, Vibration and Acoustic Studies on Helicopters; and under internal U. S. Army Electronics Command, Engineering Support Services Department R&D DA Task No. 1H6 34301 D244 05 01, Airborne Shock and Vibration Study Program.

The helicopter was provided by the 55th U. S. Army Aviation Battalion, 3rd Corps, Fort Hood, Texas. The helicopter was piloted by Lt. Arthur Smaagaard, D Troop, 1st Calvary, at Fort Hood, Texas.

This report was submitted by the authors in February 1974.

SUMMARY

Vibration and acoustic measurements were made on an OH-6A helicopter equipped with and using the XM-27 Armament system to determine the vibration and acoustic environment throughout the vehicle. Tape recordings from 60 accelerometers and 11 microphones were made during all flight conditions including gunfire. Spectrum analyses were performed to obtain vibratory double amplitude (DA), acceleration power spectral density (PSD), and sound pressure level (SPL) versus frequency. Also, amplitude probability density (APD) plots are included. Measured vibration and acoustic data are compared with military standards and specification requirements.

SECTION I

INTRODUCTION

This report presents OH-6A Helicopter vibration and acoustic data obtained from the second of three flight surveys planned jointly by the Air Force Flight Dynamics Laboratory and the U. S. Army Electronics Command. The first in the series of helicopter vibration and acoustic study reports was AFFDL-TR-73-160, "Vibration and Acoustic Environment of the UH-1C Helicopter Configured With and Using M-5 and XM-21 Armament," February 1974. The third report is a complete acoustic and vibration survey of the AH-1G helicopter to be published in 1975. The objectives of the helicopter study programs are to obtain vibration, acoustic, and shock data suitable for (1) establishing realistic test methodologies, (2) developing and verifying vibration prediction methods applicable to rotor powered aircraft, (3) updating specifications, and (4) obtaining human acoustic environmental data.

SECTION II

VEHICLE DESCRIPTION, INSTRUMENTATION, FLIGHT MEASUREMENT PROCEDURES, DATA REDUCTION & PRESENTATION

1. VEHICLE DESCRIPTION

The OH-6A is a single-engine, four-place, helicopter manufactured by the Hughes Tool Company. Primary missions of this helicopter are visual observation, target acquisition, reconnaissance, and command control. When equipped with the XM-27 armament subsystem, it is capable of defense against ground based fire from automatic weapons and small arms. It is powered by an ALLISON T63-A-5A turbine engine rated at shaft horsepower (shp) at 600 (100%) rpm. Its maximum gross weight is 2400 pounds. The diameters of the four-bladed main rotor and the two-bladed tail rotor are 26 feet, 4 inches and 4 feet, 3 inches, respectively. Under rated power the main rotor operates at 475 rpm and the tail rotor at 3020 rpm. The fundamental frequencies of the main and tail rotors are 32 Hz and 100.6 Hz, respectively. Helicopter Serial No. 12954 used for this flight test program was equipped with the XM-27 armament subsystem consisting of a GAU 28/A 7.62 millimeter machine gun capable of firing rates of 2000 or 4000 rounds per minute. Photographs of the helicopter with doors on, and doors off, are shown in Figures 1 and 2.

2. INSTRUMENTATION

The flight instrumentation consisted of (1) 48 Endevco Corporation 2200 series piezoelectric accelerometers, (2) 12 Gulton Industries Model LA550203 low frequency accelerometers, (3) 11 Gulton Industries Model 229507 crystal microphones, (4) a 12-channel, 6-position selector switch, (5) a low frequency accelerometer attenuator box, (6) a 13-channel signal conditioning unit containing Fairchild Model AD0-24 operational amplifiers with external circuitry for continuously adjustable gain, (7) a voice microphone, (8) a magnetic sensor for indicating main rotor position and speed and (9) a 14-channel Genisco Inc. Model 10-110 tape recorder utilizing 30 ips tape speed and 54K Hz center frequency FM record amplifiers. Figure 3 shows the data recording system installed in the passenger compartment of the helicopter.

The 48 piezoelectric accelerometers were mounted at 16 points of interest, in groups of three, and oriented to sense vibration along the three major axes of the helicopter. Low frequency accelerometers were mounted on the instrument panel, right and left side of the cabin floor, fuselage-tail section interface, and tail boom. Microphones were mounted externally along the longitudinal axis and on the upper surface of the helicopter to sense blade passage excitation, externally on the armament mount, and internally on the pilot's and copilot's helmets, rear cabin bulkhead, and avionics compartment. A complete listing of all pickup locations, types, and identification numbers is contained in Table II. Figures 4, 5, and 6 are aircraft drawings showing the locations of piezoelectric accelerometers, low frequency accelerometers, and microphones, respectively. Figures 7-33 are photographs of pickup installations. All pickups were calibrated in the laboratory using the same cables, connections, and mounting brackets used during flight measurements. Accelerometer calibrations were conducted using a Calidyne Model 182 vibration exciter and an Unholtz-Dickie Model 610 RMG Dial-A-Gain vibration monitor. A General Radio Type 1552B sound level calibrator driven by a General Radio Type 1307A oscillator was used for calibrating the Gulton microphones. The frequency responses of the three types of pickups are summarized as follows:

Endevco Accelerometers: Flat within $\pm 5\%$ from 2-6000 Hz

Gulton Microphones: Flat within ± 2 dB from 2-6000 Hz and within ± 3 dB to 10K Hz

Low Frequency Accelerometers: Flat within $\pm 5\%$ from 0-60 Hz, and within ± 3 dB to 160 Hz

The accuracy limitations of the flight measurement system are due to error contributions from transducers, signal conditioning equipment, and tape recorder. The maximum error of any one of these elements is unlikely to exceed $\pm 5\%$ of full scale output. A reasonable estimate of the maximum likely overall error is the root-mean-square of the errors of the three contributors or $\pm 8.7\%$ of full scale output.

3. FLIGHT MEASUREMENT PROCEDURES

A total of four flights were conducted to obtain vibration and acoustic data. Measurements were made during all normal flight conditions with the cabin doors installed at a gross weight of 2300 pounds. Normal flight conditions included ground runup, takeoff, climb, level flight at various speeds and altitudes, hover, descent, autorotation, combat approach to landing, turns, sideward flight, and rearward flight. Measurements also were made with the cabin doors removed to simulate combat environment during level flight at 40, 80, and 100 knots IAS at 500 and 5000 feet altitude, and during combat approach maneuvers at maximum speed and rate of descent.

Measurements were made during gunfire at 2000 and 4000 rounds per minute with the doors installed and with the doors removed. Recordings were made with the gun deflected downward 20° or with the helicopter in a 20° dive. Table III contains a summary of flight test conditions.

For each flight condition, a 12-channel data sample of 20 seconds duration was generally recorded for each of the six selector switch positions. Thus, the output of each of the transducers was generally recorded for each flight condition. Flight conditions and aircraft performance parameters were recorded on a voice channel. Recorded information included altitude, airspeed, rate of climb or descent, pitch angle, roll angle, engine speed, main rotor speed, torque pressure, fuel weight, outside air temperature, and tail pipe temperature. The output from the rotor speed/position pickup was superimposed on the voice channel.

4. DATA REDUCTION PROCEDURES

In view of the very large amount of flight data gathered and other high priority work load, it was decided to screen the data and analyze only those records required to adequately define the amplitude range of the helicopter vibration and acoustic environment. This screening process involved playing back all records on a Honeywell Model 3170 tape

record/reproduce system and measuring the overall RMS levels on Bruel & Kjaer (B&K) Type 2305 level recorders. Data samples necessary to establish maximum, minimum, and average levels, and to indicate variation in environmental levels with flight parameters, were selected and analyzed in detail. Flight conditions selected for data analysis are described in Table IV.

Five-second loops of flight recordings were dubbed from the tape reels using the Honeywell record/reproduce system. Exceptions to this were that loops of gunfire tapes were of shorter duration due to the three-second firing limit of the gun. Piezoelectric and low frequency accelerometer data were played back on a Honeywell loop machine and analyzed on a Honeywell Model 9050, six-channel automatic wave analyzer. Performance characteristics of this analyzer were adjusted as follows:

TABLE I
HONEYWELL MODEL 9050 ANALYZER CHARACTERISTICS

Effective Bandwidth (Hz)	Frequency Range (Hz)	True Averaging Time (Sec)	Scan Rate (Hz/sec)
3	0-160	5	0.2
15	0-500	4.4	1.6
35	501-1000	2.0	7.0
75	1001-6000	1.0	22

The analyzer characteristics listed for the three Hz effective bandwidth were used for analyzing low frequency accelerometer data only. The analyzer produced transducer voltage levels versus frequency on six modified Brown strip-chart recorders in the frequency range of 0-6000 Hz. Data points were manually extracted at each frequency marker (each 20 Hz from 0 to 400 Hz; each 50 Hz from 401 to 1000 Hz; each 100 Hz from 1001 to 2000 Hz; and each 200 Hz from 2001 to 6000 Hz). Significant peaks in the spectrum also were tabulated.

The microphone data were analyzed on one-third octave B&K Type 2111 audio frequency spectrometers. Spectrometer outputs were recorded on B&K Type 2305 level recorders. Controls on the level recorders were set to obtain rms outputs and averaging time of 2.5 seconds. Data points from the level recorder charts were tabulated for each one-third octave in the frequency range of 12.5 to 10,000 Hz.

The tabulated voltage levels and frequencies from the spectrum analyzers and other identifying information were punched into IBM data cards. Corresponding decks of master cards containing descriptive information on pickup identification and sensitivity, flight conditions and vibration sources also were produced. The IBM card information together with formulas for computing double amplitude in inches, acceleration in g units, power spectral density in g^2/Hz and sound pressure level in decibels (re $0.0002 \text{ dynes/cm}^2$) were fed to an IBM 7094 computer. Plot tapes were then generated by the computer which were used with a Calcomp Model 563 automatic plotter to obtain plots of double amplitude, power spectral density or sound pressure level versus frequency.

Amplitude probability density (APD) analyses of selected accelerometer outputs were conducted with a Gulton Industries statistical analyzer. The statistical analyzer controls were adjusted to obtain an amplitude range of ± 3 standard deviation units, a smoothing time constant of three seconds, and a scanning time of 450 seconds. The analog outputs of the analyzer (probability density and amplitude) were plotted on a Mosley Model 2DR-2, X-Y recorder. APD plots of both overall and narrowband filtered acceleration signals were obtained. Narrowband filtering was accomplished with a Spectral Dynamics SD-101A analyzer. Filter bandwidths of 5, 10, and 20 Hz were used in the frequency range of 5 to 100, 101 to 200, and 201 to 6000 Hz, respectively.

5. DATA PRESENTATION

Each frequency spectrum plot in this report portrays a summary of vibration or acoustic levels measured under various flight conditions by all transducers in one group, in one zone, or on the entire helicopter. Each group plot summarizes the data from either (1) a group of three piezoelectric accelerometers measuring vertical, lateral, and fore and aft vibration, (2) a group of one to three low frequency accelerometers, or (3) one microphone. Zone plots cover the (1) nose section and cockpit, (2) passenger compartment, (3) engine-transmission compartment, and (4) tail section.

Vibration data are presented in two forms: (1) double amplitude (DA) versus frequency, and (2) power spectral density (PSD) versus frequency. Low frequency and piezoelectric accelerometer data are plotted in the frequency ranges of 5 to 160 Hz and 5 to 6000 Hz, respectively. Sound pressure level (SPL) in db re 0.0002 dynes/cm² is plotted in one-third octave bands in the frequency range of 12.5 to 10,000 Hz. Percentile type plots are used for portraying all spectrum information. Each of these plots contains curves encompassing 99% and 90% of the data as well as curves for maximum, average, and minimum levels. For plotting purposes, the vibration spectrum is divided in frequency bands approximately one-third octave wide. In those instances where there are less than 100 data points in a frequency band, the maximum and the 99% level are plotted at the same point. If there are less than ten data points in a frequency band, the 90% level also coincides with the maximum.

Both double amplitude and power spectral density plots, with and without gunfire, have been prepared for each accelerometer. However, since there are a total of 236 of these plots, and since most recipients of the report would not require this data, plots for individual accelerometers are not included in this report. Organizations having a requirement for these plots may obtain copies by a special request to the Air Force Flight Dynamics Laboratory, (Attn: FYT), Wright-Patterson AFB, Ohio 45433, or from the U. S. Army Electronics Command (Attn: AMSEL-RD-GDM), Fort Monmouth, New Jersey.

AFFDL-TR-74-81

Separate plots are made for all flight conditions except gunfire and for gunfire. A summary of the various types of plots and corresponding figure numbers is contained in the latter part of the List of Illustrations.

SECTION III

RESULTS

1. GENERAL

In the following discussion of results, reference is made to vibration amplitudes in various frequency bands. These vibration amplitudes obviously are dependent on analyzer bandwidths. In applying these data to the development of test criteria, the bandwidths defined in Section II.4 of this report should be considered. Also the predominantly random nature of the vibration at frequencies above approximately 200 Hz should influence test criteria derived from these data.

2. VIBRATION WITHOUT GUNFIRE

Zone plots of double amplitude versus frequency (Figures 34-37) were compared with the sinusoidal vibration test curve, for equipment designed for helicopters, from MIL-STD-810B, Reference 1 (Figure 514-1, Curve M). This test curve was drawn on a transparent overlay and used to examine the DA plots. No consideration is given to time compression or fatigue testing techniques. This curve also is shown in Figure 34 which illustrates vibration amplitudes without gunfire in the nose section and cockpit of the helicopter where most of the electronic equipment is located.

Inspection of Figures 34-37 shows that the bulk of the data falls below the test curve in the frequency range below 500 Hz. Exceptions are listed as follows:

a. Figure 34, Nose Section and Cockpit: 0.12 inch DA at 10 Hz and 3g at 35 Hz.

b. Figure 36, Engine-transmission Compartment: 0.14 inch DA at 10 Hz, 3g at 30 Hz, and 4g at 40 Hz.

c. Figure 37, Tail Boom: 0.95 inch DA at 10 Hz, 3 to 4g at 20 to 50 Hz, and 6 to 10g at 150 to 400 Hz.

These figures also show that vibration amplitudes are much higher in the engine-transmission and tail boom areas than in the forward areas of the helicopter. It should be noted that although the MIL-STD-810B test curve extends to only 500 Hz, significant vibration exists at frequencies up to 5000 Hz. For example, Figure 35 indicates 2g from 700 to 900 Hz and 4g at 5000 Hz.

Figures 42-63 are group plots of DA versus frequency for each accelerometer location. These plots were inspected to obtain maximum amplitudes occurring in areas where electronic equipment is located. These maximum amplitudes are well below the MIL-STD-810B test curve except at 10 Hz where the test curve is exceeded slightly. Above 500 Hz (beyond the test curve) amplitudes are below 2g in electronic equipment areas.

In Figures 60 and 63, the vibration amplitudes obtained from low frequency accelerometers located on the cabin floor are compared with the maximum vibration requirements of MIL-H-8501A, Reference 2, Paragraph 3.7.1(C), for personnel stations in helicopters. The maximum amplitudes permitted by Paragraph 3.7.1(C) of MIL-H-8501A are 0.3g at frequencies below 44 Hz and 0.003 inch double amplitude at frequencies above 44 Hz. These amplitudes are exceeded on the OH-6A cabin floor in the frequency range of 18 to 55 Hz. Figure 60 for the right side of the cabin floor shows 1.2g at 35 Hz, 0.4g at 45 Hz, and 0.6g at 55 Hz. Figure 63 for the left side of the cabin floor indicates 0.5g at 18 Hz and 0.7g at 35 Hz. Otherwise vibration levels fall below MIL-H-8501A requirements.

A summary of vibration levels occurring on the entire helicopter for all flight conditions except gunfire is shown in the DA plot of Figure 156. This figure indicates maximum amplitudes near 5g at frequencies up to 200 Hz, and amplitudes near 10g at frequencies between 200 and 5000 Hz. A maximum amplitude of 50g is indicated at 5000 Hz.

The 99% curve (curve which includes 99% of the measured points) never exceeds 5g; the 90% curve is generally below 1g; and the average curve is generally below 0.5g.

The PSD group plots for flight conditions without gunfire are included in Figures 86-107. Seven of these 22 figures indicate maximum levels greater than $1g^2/Hz$, eight indicate levels between 0.1 and $1g^2/Hz$ and seven are below $0.1g^2/Hz$. Zone plots for PSD's without gunfire are shown in Figures 148-151 and the PSD summary plot for the complete helicopter is contained in Figure 158. These plots may be used to quickly determine levels that may occur in the various zones of the aircraft.

3. VIBRATION WITH GUNFIRE

Figures 38-41 are zone plots of DA versus frequency with gunfire. Comparison of these plots with those without gunfire (Figures 34-37) illustrate that amplitudes are much higher with gunfire at all locations except the tail boom. For example, Figure 34 for the nose section and cockpit without gunfire, indicates maximum amplitudes between 0.3 and 3g in the frequency range of 30 to 1000 Hz. Figure 38 for the same zone with gunfire indicates amplitudes ranging from 2 to 20g in the same frequency range. Group plots of DA versus frequency (Figures 64-85) also show much higher amplitudes during gunfire for all locations except the tail boom. The increase in vibration amplitudes from gunfire is greatest in the electronics compartment on the left side of the aircraft. This increase is illustrated by comparing Figures 47 and 48 for flight conditions without gunfire with Figures 69 and 70 for gunfire conditions. For example, Figure 47 indicates a maximum of 0.6g at 44 Hz while Figure 69 for the same location with gunfire indicates 20g at the same frequency. This location is on light structure and slightly forward of the minigun where high level gunfire vibration was expected. Comparison of PSD zone plots with gunfire (Figures 156-159) and PSD group plots with gunfire (Figures 108-219) with corresponding plots without gunfire (Figures 152-155 and 86-107) also show a large increase in vibration amplitudes except for positions on the tail boom.

4. SOUND PRESSURE LEVELS WITHOUT GUNFIRE

Figures 130-138 are sound pressure (SPL) plots without gunfire. The levels measured in the cabin area were compared with the requirements of MIL-A-8806A, Table IIIA, Reference 3 (for maximum continuous power), which applies to occupied spaces in aircraft where personnel must wear helmets. MIL-A-8806A requirements are specified in octave bands, while data in this report are presented in one-third octave bands. It was necessary to reduce the MIL-A-8806A levels by 4.8 db to obtain equivalent one-third octave band levels for making direct comparisons of specification levels with plotted data. These reduced levels are superimposed on Figures 134 and 135 for the pilot's and copilot's helmets. These figures illustrate that MIL-A-8806A levels are exceeded at the pilot's helmet by 2 to 5 db in frequency bands of 31.5, 100, 160, and 400 Hz, and by as much as 12 db at frequency bands above 1600 Hz. At the copilot's helmet, MIL-A-8806A levels are exceeded by 2 to 4 db at frequency bands of 31.5, 400 and 1600 Hz, and by as much as 10 db at frequencies above 1600 Hz. The revision to MIL-A-8806A, Reference 4, (MIL-S-008806B(USAF), Curve F) permits higher levels in occupied areas than those permitted by MIL-A-8806A. These higher levels exceed essentially all sound pressure levels measured at the pilot's and copilot's helmets without gunfire.

Figure 132 shows SPL's measured internally in the forward electronics compartment. One-third octave levels in this compartment are below 120 db and the maximum overall level is approximately 122 db. Since MIL-STD-810B, Reference 1, states that acoustic qualification tests should not be required for equipment installed where overall sound levels are below 130 db, acoustic tests do not appear to be justified by the "no gunfire" environment in the electronic equipment compartment.

Figures 134-138 are SPL plots from external microphones located on the nose tip, XM-27 armament pod, and on top of the fuselage. Maximum SPL levels for each of these locations occur in the 31.5 Hz frequency band (blade passage frequency), and levels range from 135 to 142 db. Overall levels at these locations range from 138 to 146 db.

5. SOUND PRESSURE LEVELS WITH GUNFIRE

Plots of SPL versus frequency with gunfire are contained in Figures 139-147. Figure 142 for the pilot's helmet shows that the spectrum peaks in the one-third octave band of 40 Hz at a level of 138 db, and the overall level is 144 db.

Figure 141 for the electronics compartment with gunfire illustrates one-third octave levels of approximately 135 db at frequencies of 100 and 500 Hz, and an overall level of approximately 140 db is indicated. According to MIL-STD-810B, acoustic qualification tests might be appropriate for acoustically sensitive equipment where noise levels are this high.

Sound pressure levels measured externally during gunfire are shown in Figures 143-147. Comparison of these levels with those shown in Figures 134-138 (without gunfire) show that the levels at the nose tip and armament pod are as much as 30 db higher during gunfire in the frequency range above 31.5 Hz. At locations farther aft on the fuselage, gunfire effects are less pronounced and levels do not increase greatly with gunfire. For example, comparison of Figure 147 with Figure 138 (Sta. 243) shows that maximum spectrum levels with gunfire are approximately the same as those obtained without gunfire.

6. AMPLITUDE PROBABILITY DENSITY

Knowledge of the relative amplitudes of sinusoidal and random components of flight vibration environment is necessary for the development of appropriate vibration testing criteria. The shapes of amplitude probability density (APD) plots of flight vibration are utilized to evaluate the sinusoidal versus random content of measured vibration. Standard APD plots of sinusoidal, random, and mixtures of sinusoidal and random signals were first prepared to illustrate shapes of APD curves for a wide range of mixtures. The characteristic shapes for a sine wave and for a random Gaussian signal are illustrated in Figures 161 and 162, respectively. Plots also were prepared for a mixture of a

100 Hz sine wave and a random signal having a flat spectrum from 20 to 1000 Hz. Figures 162-165 show that the random component must be reduced to less than the sinusoidal component before the shape of the APD plot differs appreciably from that for a pure random plot. The random component was reduced to one-fifth that of the sinusoidal component before the shape of the APD plot appeared to be more sinusoidal than random. Thus, the APD plot is a sensitive indicator of the presence of random components, but it is a relatively insensitive indicator of sinusoidal components.

Figures 166-175 are APD plots of vibration measured in the forward electronics compartment or on the cabin floor during an attack maneuver at 110 knots or during gunfire at 4000 rounds per minute. APD plots also were obtained for other locations and flight conditions, but since they duplicate the results illustrated in the above figures, they are not included herein. Comparison of the APD plots of Figures 166-175 with the mixed sinusoidal and random plots shows that the OH-6A vibration is predominantly sinusoidal in frequency bands up to 200 Hz. Vibration generally is more nearly random than sinusoidal in frequency bands above 200 Hz. These statements are true for all flight conditions, including gunfire.

SECTION IV

CONCLUSIONS

In the frequency range of 5 to 500 Hz for flight conditions without gunfire, vibration levels on the OH-6A helicopter in areas where electronic equipment is mounted generally are below the applicable sinusoidal vibration test curve of MIL-STD-810B (Reference 1).

Significant vibration occurs throughout the OH-6A helicopter in the frequency range of 500 to 5000 Hz. This frequency range is well beyond the 500 Hz upper limit of the test curve of MIL-STD-810B for helicopter equipment.

The vibration levels specified in MIL-H-8501A, Paragraph 3.7.1(C) for personnel stations in helicopters are exceeded during flight conditions without gunfire on the OH-6A cabin floor in the frequency range of 18 to 55 Hz. However, levels generally are below 1g.

OH-6A vibration levels increase considerably during gunfire at all locations except the tail boom. The greatest increase occurs forward of the minigun in the left side of the electronics compartment. In the 44 Hz frequency band at this location, the vibration level increases from 0.6g to 20g as the gun is fired.

Sound pressure levels without gunfire in the OH-6A cabin exceed levels specified in MIL-A-8806A, Table III, by 2 to 12 db in several frequency bands. However, these levels rarely exceed those specified by a revision to this specification, MIL-S-008806B(USAF), Reference 4, Curve F. Sound pressure levels increase during gunfire in the cabin area by as much as 30 db in some frequency bands.

Sound pressure levels without gunfire in equipment compartments are too low to cause significant equipment problems. Gunfire induced sound pressure levels (140 db, overall) could cause malfunctions of acoustically sensitive equipment.

AFFDL-TR-74-81

In frequency bands below 200 Hz, both with and without gunfire, OH-6A vibration is predominantly sinusoidal. In frequency bands above 200 Hz, vibration is more random than sinusoidal.

SECTION V

RECOMMENDATIONS

New vibration test criteria for helicopter equipment should be developed from the data analyses presented in this report. Separate sinusoidal vibration tests, at frequencies below approximately 200 Hz are recommended for different zones, as it is unrealistic to design and test all equipment according to data from the worst zone when particular equipment items will be installed in a milder vibration environment. These sinusoidal vibration tests should provide for dwell testing at blade passage frequencies and their harmonics. Since the data show that the helicopter vibration environment above 200 Hz is predominantly random, a random vibration test should be developed for the high frequencies. Also, separate tests should be developed for the gunfire vibration condition since the magnitudes of this type of vibration are significantly greater in severity than the regular flight vibration.

Climb	35	300-700	All
Right turn, 30°	55	500	All
Right turn, 55°	60	500	All
Left turn, 30°	55	500	All
Left turn, 60°	50	500	All
Autorotation	68	4000-0	All

TABLE IV (Contd)

Condition	IAS (Knots)	Altitude (Feet)	PUID's
Standard descent	58	4000-0	All
Combat approach, swing	120	2500-0	All
Combat approach, spiral	100	5000-0	All
Combat approach, spiral, doors off	98	5000-0	All
Attack maneuver	110	500	All
Gunfire, 2000 rounds/min., 20° gun angle	110	500	All
Gunfire, 4000 rounds/min., 20° gun angle	110	500	All
Gunfire, 2000 rounds/min, 20° gun angle	60	500	49-60
Gunfire, 4000 rounds/min, 20° gun angle	60	500	49-60
Gunfire, 2000 rounds/min, 20° dive angle	110	800-500	All
Gunfire, 4000 rounds/min., 20° dive angle	110	800-500	1-36
Gunfire, 2000 rounds/min., 20° dive angle, doors off	110	800-500	All
Gunfire, 4000 rounds/min., 20° dive angle, doors off	110	800-500	1-12
